Mid-term Workshop Agenda

Tuesday, November 8, 2016

10.00-10.15 Welcome address (Agenda, timetable, MIGHEAL research objectives)

Dr. Terje Andreas Eikemo, Professor, Department of Sociology and Political Science, Norwegian University of Science and Technology, MIGHEAL Scientific Coordinator

10:15 -10:30 MIGHEAL Fieldwork results

Theoni Stathopoulou, Research Director, National Centre for Social Research-EKKE, MIGHEAL Scientific Coordinator

10:30-11:20 Theoretical perspectives on migration and health

Per Stornes, MIGHEAL Researcher, PhD candidate, NTNU

Jennifer Cavounidis, Senior Research Fellow, Centre of Planning and Economic Research (KEPE) - MIGHEAL Advisory Board

Roundtable discussion (20 min.)

11:20- 11.40 Coffee Break

11:40- 12:30 General differences in the migrant and native born population

Native and migrant populations usually differ in many respects, such as age, gender, education, income and occupation distribution. The presentation will review demographic considerations when doing survey research on immigration health in MIGHEAL, and make suggestions for analytical approaches.

Per Stornes, MIGHEAL Researcher, PhD candidate, NTNU

Roundtable discussion (20 min.)

NATIONAL CENTRE FOR SOCIAL RESEARCH

12:30-12:45 Coffee Break

12:45 – 13:45 Migrant and native population health status

An integrated overview of migrant and native population:

- health outcomes (physical and mental)
- health care utilization and
- access to health services

This presentation goes towards both the objective to provide evidence of migrants' health status, health care utilization and access to health services, and to compare migrant health status and care needs with native born population health status and care needs.

Per Stornes, MIGHEAL Researcher, PhD candidate, NTNU

John Yfantopoulos, Professor, School of Economics and Political Science, University of Athens – MIGHEAL Advisory Board

Roundtable discussion (30 min.)

13:45-14:30 Light Lunch

14:30-15.20 Barriers to access and utilization among migrants

One of MIGHEAL's research objectives is to identify barriers to access and utilization of health services among migrants. The presentation will give a brief review on theories and research on the topic, and present some results from the data.

Per Stornes, MIGHEAL Researcher, PhD candidate, NTNU

Roundtable discussion (20 min.)

MINISTRY OF EDUCATION, RESEARCH

15:20-16:40 Comparisons with findings in the European Social Survey health module.

The MIGHEAL survey is based on a scaled down version of the European Social Survey 7, with most of the questions from the rotating health module intact. To contextualize the results from MIGHEAL, some comparisons will be made to the results from ESS. This is important in order to assess the validity and reliability of MIGHEAL data.

Per Stornes, MIGHEAL Researcher, PhD candidate, NTNU

Anastasia Kostaki, Professor, Head of Statistics Department, Athens University of Economics and Business - MIGHEAL Advisory Board

Roundtable discussion (20 min.)

16:40 – 17:30 Discussion on the analytical strategy

19:30 Dinner

Wednesday, November 9, 2016

Wrap-up (next steps)

- a) main conclusions regarding the analytical strategy of MIGHEAL data.
- b) final report
- c) short policy paper
- d) paper in peer review journal
- e) other dissemination activities

Summary

Mid-term workshop of the MIGHEAL project was held on November 8-9, 2016 in Trondheim at the NTNU offices with the participation of NTNU and EKKE research team as well as the members of the Expert Panel. During the mid-term workshop, participants discussed the results of fieldwork, the preliminary statistical findings, and the optimal analytical strategy.

The presentations delivered and the discussion among participants addressed the following issues:

- a) MIGHEAL fieldwork results:** Survey design, sampling frame, MIGHEAL data
- b) Theoretical perspectives on migrant health:** Theoretical considerations to be made when researching migrant health.
- c) General differences in the migrant and native born population:** Demographic aspects of the MIGHEAL sample, as compared to figures from Eurostat.
- d) Migrant and native population health in MIGHEAL:** Main results of the preliminary analysis of MIGHEAL data.
- e) Barriers to access and utilization among migrants:** Prevalences of measures on barriers to access that were added specifically to the MIGHEAL survey.
- f) Comparisons with findings in the European Social Survey health module:** Population level comparisons with outcomes from the European Social Survey.

NATIONAL CENTRE FOR SOCIAL RESEARCH

1. MIGHEAL Fieldwork results

1.1. Sampling method

This part of the report is based on the presentation of Theoni Stathopoulou, Scientific co-ordinator of the MIGHEAL (αντίστοιχα να βάλουμε και στα άλλα)

Sample selection was based on geographical stratification on a NUTS2 level proportionally to the population data of urban areas and census enumeration in order to establish a probability sample for the survey. Nevertheless, and on the contrary of the procedures usually employed for social surveys, the PSU selection for enumeration didn't derive by a sampling framework incorporating all possible areas/ settlements and randomly selecting PSU's but by approaching the areas with higher density of target groups according to CENSUS 2011.

1.2. Sampling frame

Sample population was divided into two groups, based on respondents' citizenship: migrants and non-migrants. Migrant is a third country national who is not a citizen of an EU country (within the meaning of Article 20 paragraph 1 of the Treaty on European Union). The GDP per capita criterion¹ was applied to exclude migrants from developed countries. The sampling specifications for native and migrant population were set as follows:

a) Native Population: individuals aged 15 or over living in private households.

Sampling/ Enumeration: Enumeration precedes fieldwork in order to establish a probability sample for the survey. The PSU selection for enumeration is derived by a sampling framework incorporating all possible areas/ settlements and randomly selecting PSU's (according to CENSUS 2011). After enumeration, addresses are randomly

¹ According to the World Bank, high income countries are those with a GDP per capita of 37.755 current US\$ or more.

**MINISTRY OF EDUCATION, RESEARCH
AND RELIGIOUS AFFAIRS
GENERAL SECRETARIAT FOR RESEARCH
AND TECHNOLOGY
PROGRAMME OPERATOR**

selected and included in the sample. Random selection of respondent (KISH Grid) when an eligible household is identified. Selected households and selected respondents are not replaced, at least 4 visits/ contacts made to each selected household before appointing a final code to it.

b) Migrant Population: individuals aged 15 or over living in private households having sufficient knowledge of Greek language.

Probability sample: The PSU selection for enumeration is not derived by a sampling framework incorporating all possible areas/ settlements and randomly selecting PSU's but by approaching the areas with higher density of target groups (according to CENSUS 2011).

Focused enumeration (cluster sampling of areas with migrant population according to 2011 CENSUS):

For ensuring the comparability of MIGHEAL with ESS data, the sample of migrant population was drawn using a multi-stage stratified sampling technique. More specifically, the 13 administrative regions of the country were considered as strata, and the sample size of each region was proportional to the size of the migrant population in each region according to the 2011 population census. In total 80 sampling sites from the 13 strata were selected in order to identify individuals who belong to the survey population of migrants. For the native population, 80 sampling sites have also been randomly selected, close to those selected for the migrant population, in order to ensure comparability between the two population groups (matched geographic sample). In addition another 48 sampling points from the urban areas of the country have also been randomly selected, so that the resulting final sample of the native population to

NATIONAL CENTRE FOR SOCIAL RESEARCH

approximate the population distribution of the urban population of the country by region according to 2011 population census (boost sample).

The collection mode was PAPI. Fieldwork was conducted by Metron Analysis S.A. during May 19- July 28, 2016 across Greece. The achieved sample size was 1332 respondents (505 migrants/827 non-migrants) and the response rate was 50%.

1.3. MIGHEAL data

MIGHEAL survey resulted in a representative sample of 1332 individuals (505 migrants and 827 non-migrants), aged 15 or over, living in private households in major Greek cities. Respondents were divided into three groups based on citizenship: a) Greek citizens, b) Albanian citizens and c) third-country citizens corresponding to former socialist regimes of Central and Eastern Europe as well as citizens of countries of Asia, Africa and the Middle East.

A small group of second generation migrants was identified as most migrants in the sample reported first coming to Greece after 1990, in young adulthood. Because they do not hold Greek citizenship (Greek-born children of foreign citizens were denied access to Greek citizenship until a law passed by Greek Parliament in 2015 facilitated such access), we chose to assign the small number of cases of second generation migrants to groups on the basis of their citizenship. Migrant population in MIGHEAL had a mean length of stay in Greece 14 to 16 years.

2. Theoretical perspectives on migrant health

It is very hard to say anything a priori about migrant health. Migrant health might be compared to natives in country of origin, and natives in country of residence, and combinations of these. The process of migration is a process of selection. (Graph 1). How

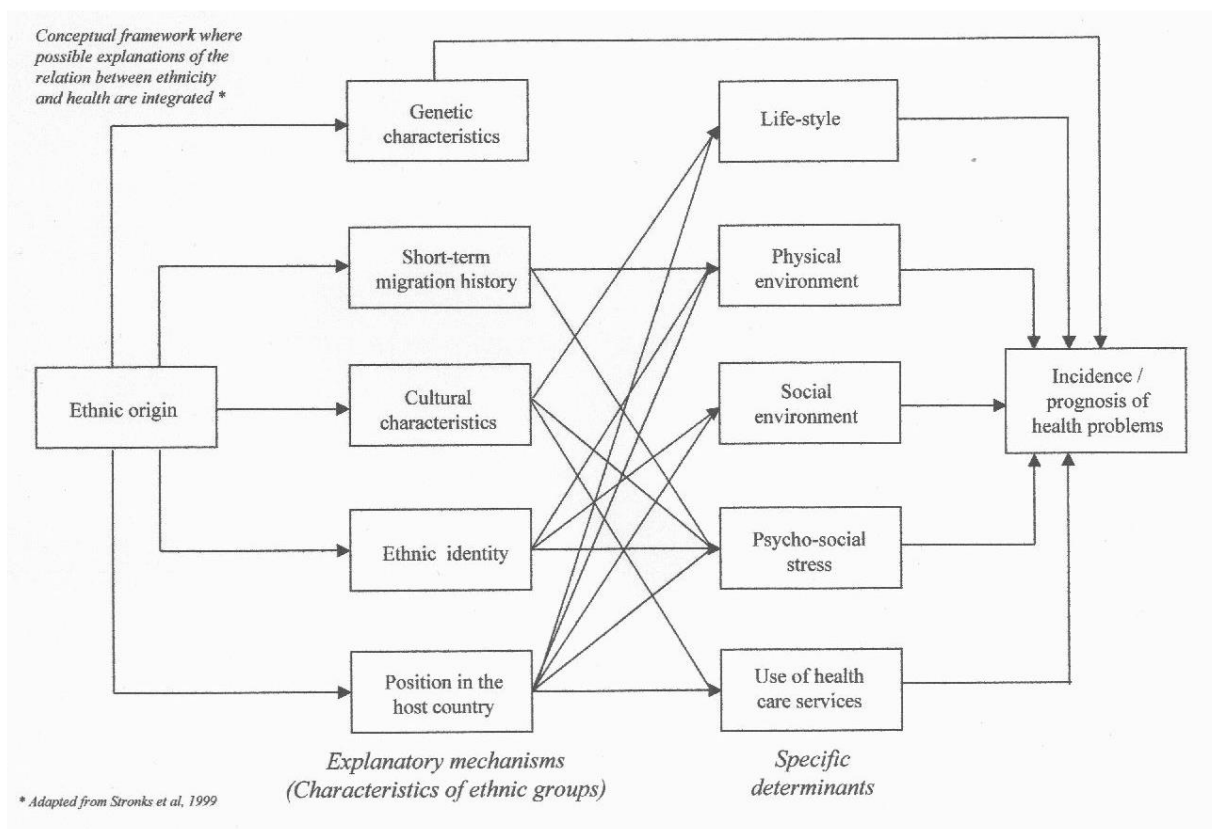

MINISTRY OF EDUCATION, RESEARCH
AND RELIGIOUS AFFAIRS
GENERAL SECRETARIAT FOR RESEARCH
AND TECHNOLOGY
PROGRAMME OPERATOR

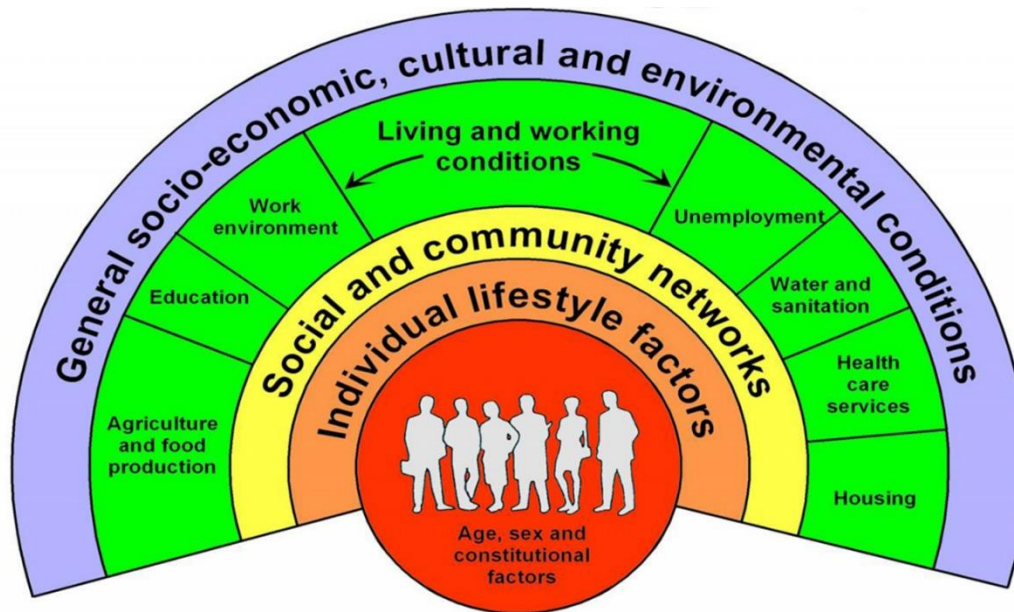

do those who leave differ from the ones who stay behind? Can there be a general model of migrant health? The study of migrant was placed into the context of social inequalities in general, illustrated by the Dahlgren and Whitehead model (Graph 2), which is one of the most important underpinnings of the research on health inequalities done at NTNU. Various study designs were covered, such as origin, destination and community effects. The healthy migrant paradox was also covered.

Graph 1: Migration and Health Model

Graph 2: Migration as an expression of social inequality in health in general

Source: Dahlgren and Whitehead, 1991

Study designs

- Origin effects: Experiences prior to migration may contribute to risk of poor health.
- Studies within groups of migrants. E.g., Poles vs Swedes in Norway.
- Destination effects: Migrants' current living conditions is influential on health.
- Studies between countries. E.g., Japanese men in Japan, California and Hawaii.
- Community effects: Specific combinations of origin and destination. E.g., Turkish men in Germany versus Turks in Turkey.

The healthy migrant paradox

The Hispanic paradox, or Latino paradox, also known as the "epidemiologic paradox," refers to the epidemiological finding that Hispanic and Latino Americans tend to have health outcomes that paradoxically are comparable to, or in some cases better than, those

MINISTRY OF EDUCATION, RESEARCH
AND RELIGIOUS AFFAIRS
GENERAL SECRETARIAT FOR RESEARCH
AND TECHNOLOGY
PROGRAMME OPERATOR

of their U.S. White counterparts, even though Hispanics have lower average income and education. The “healthy migrant effect” hypothesizes that the selection of healthy Hispanic migrants into the United States is reason for the paradox.

A second popular hypothesis, called the “Salmon Bias”, attempts to factor in the occurrence of returning home to Mexico. This hypothesis purports that many Hispanic people return to Mexico after temporary employment, retirement, or severe illness, meaning that their deaths occur on Mexican soil and are not taken into account by mortality reports in the United States. This hypothesis considers those people as “statistically immortal” because they artificially lower the Hispanic mortality rate.

Hypotheses

Migrants report *poorer* health compared with natives in their country of origin.

Migrants from Islamic countries report *better* health than from non-Islamic.

Migrants report *poorer* health as they originate from countries with political suppression.

Migrants report *better* health as the average reported health status of natives in their country of destination is higher. (Acculturation, convergence.)

Migrants report *poorer* health as natives’ attitudes are more disapproving.

Migrants report *better* health as the level of social engagement among natives is higher in destination country.

Migrants report *poorer* health as the level of social engagement among natives is higher in destination country.

Migrants from culturally similar countries have *better* health than from dissimilar countries.

Migrants report *better* health as the relative size of community increases.

Migrants report *poorer* health as the relative size of community increases.

Migrants report better health as the geographical distance between origin and destination increases, due to health selection.

3. General differences in the migrant and native born population

This part of discussion focused on the demographic aspects of the MIGHEAL sample, as compared to figures from Eurostat. The MIGHEAL sample to a large degree reflected the Eurostat figures. Some key areas were discussed in detail.

MIGHEAL data should be compared to Eurostat data² and other data to assess how representative the sample is. During the mid-term workshop a preliminary comparative analysis was presented.

Graph 3: Age structure of migrants by citizenship, EU, 2014 (Eurostat)

Distribution using population weight

Born in country	Frequency	Percent
Yes	1178	88,5
No	154	11,5
Total	1332	100

3.2. Country groups

It is observed low rate of females in group “other countries”. Moreover, there are very few 2nd generation migrants in the sample. The precise figures need to be calculated, but only 45 respondents who were born in Greece had a mother who was born abroad. The figure for fathers was 43. The analysis does not consider 2nd generation migrants further.

3.4. Age distribution in MIGHEAL using 3 country groups

MINISTRY OF EDUCATION, RESEARCH
AND RELIGIOUS AFFAIRS
GENERAL SECRETARIAT FOR RESEARCH
AND TECHNOLOGY
PROGRAMME OPERATOR

During this session, definitions of migrants were discussed. The preliminary analysis used the population groups Greeks, Albanians and third countries divided by transitional and developing countries. The EKKE team did not find the initial groupings of the Greek and migrant population satisfactory, and the EKKE and NTNU team agreed to work on a precise definition of migrant groups for the final report. The main criterion established was nationality.

A major issue in the discussion was the age distribution. The migrant sample had very low counts after age 64, and strategies for dealing with this was discussed. After deliberation, it was decided to compare Greeks and migrants in the age range 20-64. Prevalences of health outcomes would be age standardized to the migrant population. Additionally, the division into transitional and developing countries did not produce satisfactory group sizes when taking into account gender distributions.

NATIONAL CENTRE FOR SOCIAL RESEARCH

4. Migrant and native population health in MIGHEAL

During this session, the results from the preliminary data analysis were presented and discussed. Prevalence rates for self-reported health outcomes such as general health, depressive symptoms, non-communicable diseases, health care use and access, risk behaviours, and social determinants of health were presented. As these rates were not age standardized, and the country groupings were not found to be fully satisfactory, we do not summarize any findings here, expect that the prevalence of depressive symptoms was very high, compared to findings from the European Social Survey.

4.1. Mortality as the «true measure» of health / Self-reported health as a proxy

“Global self-rated health is an independent predictor of mortality in nearly all of the studies, despite the inclusion of numerous specific health status indicators and other relevant covariates known to predict mortality.” “Self-ratings represent a source of very valuable data on health status. Global self-ratings, which assess a currently unknown array of perceptions and weight them according to equally unknown and varying values and preferences, provide the respondents' views of global health status in a way that nothing else can. We would argue that the global rating represents an irreplaceable dimension of health status and in fact that an individual's health status cannot be assessed without it.” “Men who reported “Fair/Poor” SRH showed relative hazard of death of 2.13 (CI95% 1.03-4.40) and women, 3.43 (CI95% 1.23-9.59), as compared with those who reported “Very good” SRH.”³

³ Idler, E. L., & Benyamini, Y. (1997). Self-rated health and mortality: a review of twenty-seven community studies. *Journal of health and social behavior*, 21-37. <https://www.jstor.org/stable/pdf/2955359.pdf>

Probability of SRH by 4 country groups

Outcomes: 1 (Blue): Very poor health, 2 (Red): Poor, 3 (Green): Fair, 4 (Orange): Good, 5 (Green): Very poor. Unweighted, controlled for age, capped at 60.

Based on ordinal logit. Further analysis uses Fair/Poor/Very Poor as outcome.

Albanians are more likely to report very good health. Eastern=Transitional/developing.

NATIONAL CENTRE FOR SOCIAL RESEARCH

4.2. Prevalence of health outcomes and determinants using 4 country groups

All measures are estimated using sampling weights. All measures are capped at 60 years of age. Most measures are either binary originally, or have been dichotomized. Exceptions are noted. Most measures are given as prevalences in percentages within country groups. Estimates are divided into Greece, Albania, transitional and developing countries. Developed countries are excluded.

Estimates have not been age standardized. Due to the sheer number of estimates, they have not been tested using chi-square tests. Few examples of gender differences are provided.

For detailed analysis of measures and prevalences see Appendix.

4.3. Key conclusions on prevalences

- Migrants from transitional countries appear to be at higher risk of morbidity.
- Albanians overall have very good outcomes.
- Migrants tend to have lower rates of smoking and drinking, particularly those from developing countries.
- Working conditions are worse among migrants, likely due to the sectors they work in. MIGHEAL does not contain information on occupational class. Some information can be inferred from income and educational level, although migrants can be overqualified.
- The estimates hide sometimes substantial gender differences.
- Age capping has a substantial effect on estimates, especially for Greece.

MINISTRY OF EDUCATION, RESEARCH
AND RELIGIOUS AFFAIRS
GENERAL SECRETARIAT FOR RESEARCH
AND TECHNOLOGY
PROGRAMME OPERATOR

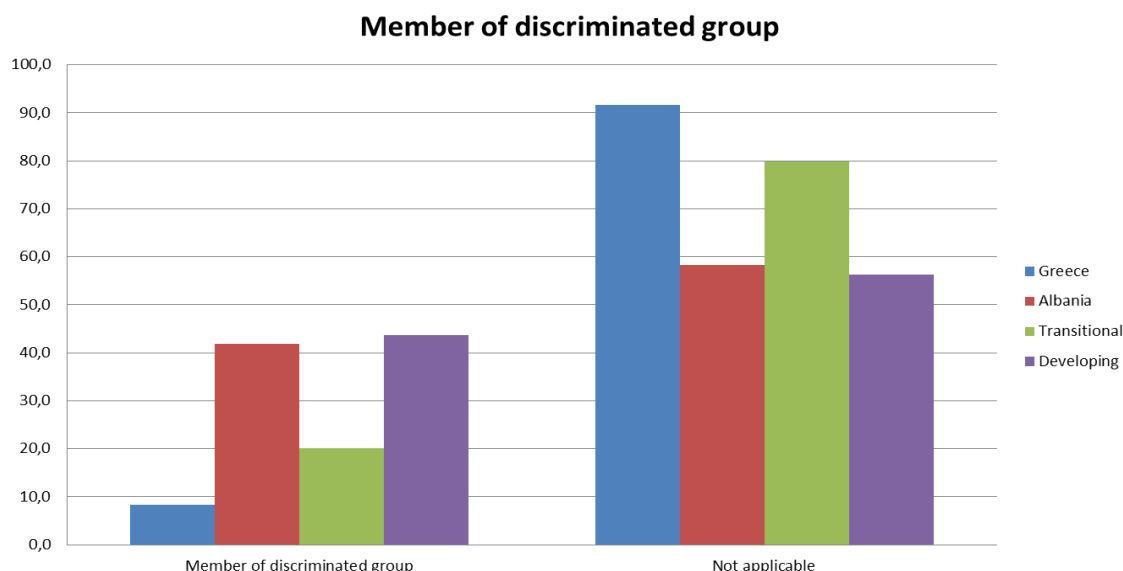

5. Barriers to access and utilization among migrants

Barrier	Description
Discrimination	Discrimination on the basis of migrant status.
Communication ability	Not speaking or understanding the dominant language to communicate with health care providers. Also cultural challenges to understanding the nuances of another culture and expressing one's problems so that they are understood and not ignored
Knowledge of the health care system	Little knowledge about how the "system" works, what rights to health care exist, and how to navigate the health care system at all levels

Source: Hacker, K., Anies, M., Folb, B. L., & Zallman, L. (2015). Barriers to health care for undocumented migrants: a literature review. *Risk management and healthcare policy*, 8, 175.

5.1. Discrimination at group level

Note: All estimates are design weighted, and capped at 60 years of age.

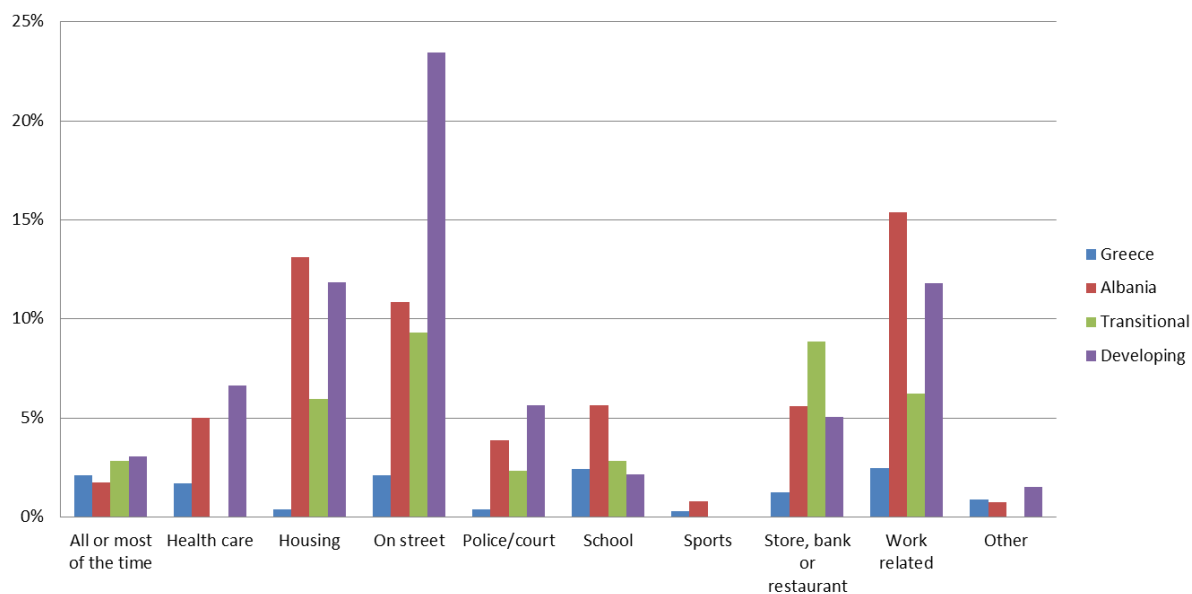

NATIONAL CENTRE FOR SOCIAL RESEARCH

Reasons for group discrimination

The most prevalent arena for discrimination is on the street, in housing and work related. Perceived discrimination in health care is relatively rare (see below).

Discrimination

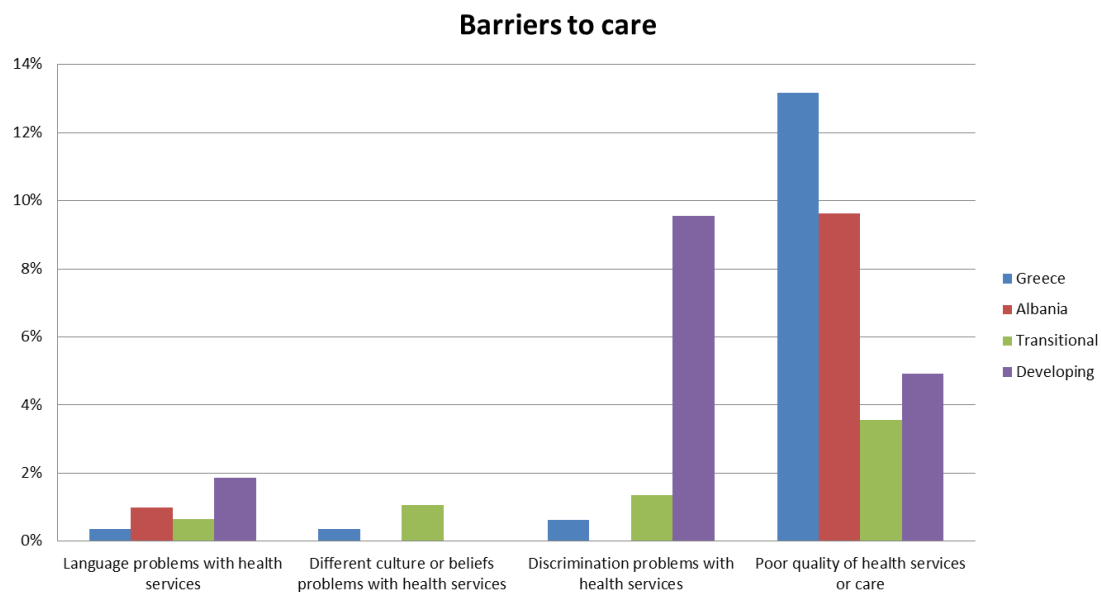

**MINISTRY OF EDUCATION, RESEARCH
AND RELIGIOUS AFFAIRS
GENERAL SECRETARIAT FOR RESEARCH
AND TECHNOLOGY
PROGRAMME OPERATOR**

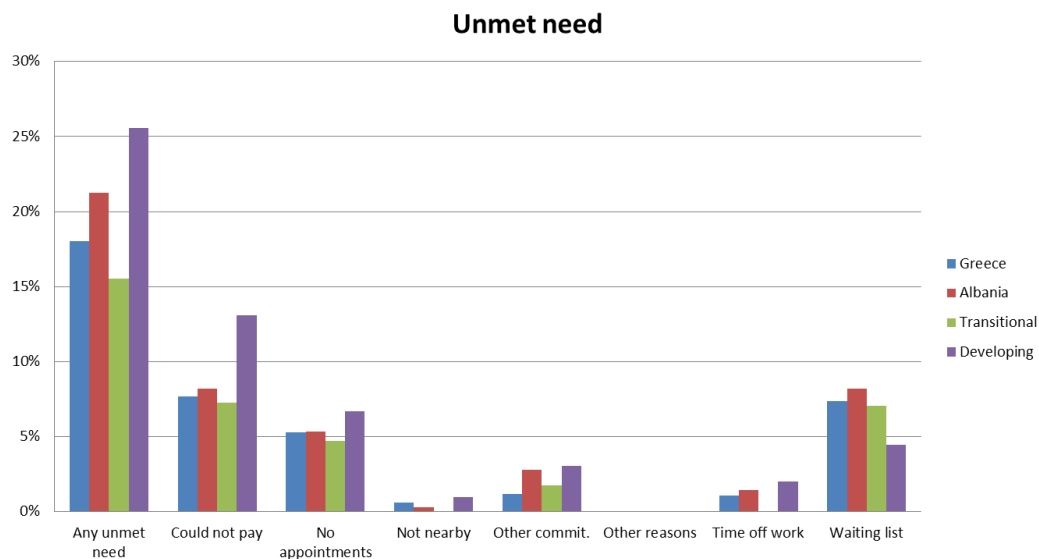

Only migrants from developing countries report problems with health services. The major problem stated is poor quality of services (See below).

“In the last 12 months ... were you ever unable to get a medical consultation or the treatment you needed for any of the reasons listed on this card?”

NATIONAL CENTRE FOR SOCIAL RESEARCH

6. Comparisons with findings in the European Social Survey health module

The last session of the mid-term workshop covered population level comparisons with outcomes from the European Social Survey. Comparing MIGHEAL depression scores (population weighted) with ESS7 data by country (post stratification weighted), the prevalence of depressive symptoms was high in Greece, as shown in the figure below.

These are mirror images of another:

Age on arrival

Education and income

Distribution of income in deciles

NB! Around 20% missing

Alternative: Financial strain

(We suggest collapsing comfortably and coping)

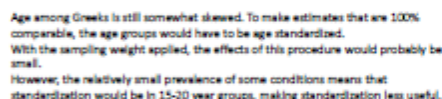

Occupation

- Age: There are very few immigrants in the older age groups, making comparisons to Greeks impossible in this category.
- An important issue to consider is whether this truthfully reflects the lack of older immigrants, and why.
- Occupation: A large portion of Greeks are retired. Most (but not all) correlates to age. Hardly any immigrants are retired, sick/disabled.

Country groupings by world regions

Here are the "other" countries grouped by geographical world region. Groups are small.

Challenges in country groupings

- "Other countries" account for only 200 cases, but constitute a very diverse group of countries, with different origin effects, and different health selection mechanisms.
- Ideally, there should be a maximum of two such country groups, considering the group sizes.
- Several options are possible, each one has potentially major consequences for the results.
- Common candidates are origin mortality rates and predominant religion in country of origin.

Further on country groupings

- **Religion:** Muslim countries fare well due to health socialization. Christians and muslims are evenly sized. However, these countries vary in other aspects. Also Greece has a low mortality rate.
- **Mortality:** Mortality rates in country of origin are associated with migrant health. However, rates in MIGHEAL are unevenly distributed.
- **Human development:** Migrants can also be seen in light of the how developed their countries of origin are. We have made some suggestions based on UN WESP: World Economic Situation and Prospects.

NATIONAL CENTRE FOR SOCIAL RESEARCH

WESP categories and HDI

- A developing country, also called a less developed country or underdeveloped country, is a nation or sovereign state with a less developed industrial base and a low Human Development Index (HDI) relative to other countries.
- A transition economy or transitional economy is an economy which is changing from a centrally planned economy to a market economy.
- Developed countries have post-industrial economies, meaning the service sector provides more wealth than the industrial sector.
- The Human Development Index (HDI) is a composite statistic of life expectancy, education, and per capita income indicators, which are used to rank countries into four tiers of human development. A country scores higher HDI when the lifespan is higher, the education level is higher, the GDP per capita is higher, the fertility rate is lower, and the inflation rate is lower.

NTNU

Further on the HDI

- Advantages of the WESP/HDI categories is that they provide a more comprehensive assessment of the countries in question.
- The WESP categories transitional/developing are quite evenly sized in MIGHEAL, and simple to collapse.
- Migrants from developed countries constitute a very small group, and could be ignored.
- Transitional/developing countries could be collapsed into a single group, due to lower scores on HDI.

NTNU

Age distribution by WESP

Supplied by Erling Landet,
NTNU.

NTNU

Countries by development

- Greece (Developed) (N=799, capped at 60: 510)
- Albania (Transitional) (N=320, capped at 60: 303)
- Western: Australia, Bulgaria, Cyprus, Germany, Spain, Finland, Italy, Lithuania, Netherlands, Romania, United States. (N=24, capped at 60: 19)
- Transitional: Armenia, Georgia, Kazakhstan, Moldova, Macedonia, Russian Federation, Ukraine, Uzbekistan. (N=80, capped at 60: 69)
- Developing: Afghanistan, Bangladesh, China, Egypt, Ethiopia, India, Iraq, Jordan, Kenya, Sri Lanka, Madagascar, Nigeria, Pakistan, Poland, Senegal, Senegal, Syria, Turkey. (N=109, capped at 60: 105)

NTNU

Summary

- Our recommendation is to cap age at around 60 to be able to reliably compare Greeks and immigrants. The small remaining numbers of Greek retired and disabled could be removed, as they skew the comparison. We suggest paid work, unemployment, and houseworkers as main occupational categories.
- Attention should be given to country groupings.
- Albanians should constitute a separate group.
- We have made some preliminary analyses based on Human Development, but will also briefly demonstrate the effects of other options.

Year of arrival and length of stay

These are mirror images of another:

Age on arrival

Education and income

Distribution of income in deciles

NB! Around 20% missing

Alternative: Financial strain

(We suggest collapsing comfortably and coping)

Occupation

- Age: There are very few immigrants in the older age groups, making comparisons to Greeks impossible in this category.
- An important issue to consider is whether this truthfully reflects the lack of older immigrants, and why.
- Occupation: A large portion of Greeks are retired. Most (but not all) correlates to age. Hardly any immigrants are retired, sick/disabled.

Here are the "other" countries grouped by geographical world region. Groups are small.

Age among Greeks is still somewhat skewed. To make estimates that are 100% comparable, the age groups would have to be age standardized. With the sampling weight applied, the effects of this procedure would probably be small. However, the relatively small prevalence of some conditions means that standardization would be in 15-20 year groups, making standardization less useful.

Migrant and native population health in MIGHEAL

MIGHEAL mid-term workshop

NTNU, November 8-9, 2016

Per Stormes, PhD student, NTNU

All estimates on prevalences, and some tables, have been supplied by Erling Landet, NTNU.

Norwegian University of Science and Technology

Measurement: self-reported health

- Mortality as the «true measure» of health
- Self-reported health as a proxy
 - "Global self-rated health is an independent predictor of mortality in nearly all of the studies, despite the inclusion of numerous specific health status indicators and other relevant covariates known to predict mortality."
 - "We conclude that self-ratings represent a source of very valuable data on health status. Global self-ratings, which assess a currently unknown array of perceptions and weight them according to equally unknown and varying values and preferences, provide the respondents' views of global health status in a way that nothing else can. We would argue that the global rating represents an irreplaceable dimension of health status and in fact that an individual's health status cannot be assessed without it."
 - Idler, E. L., & Benyamini, Y. (1987). Self-rated health and mortality: a review of twenty-seven community studies. *Journal of health and social behavior*, 21-37. <https://www.jstor.org/stable/pdf/2653356.pdf>
 - "...men who reported 'Fair/Poor' SRH showed relative hazard of death of 2.13 (95% CI 1.03-4.40) and women, 3.40 (95% CI 1.23-9.58), as compared with those who reported 'Very good' SRH."

Probability of SRH by 4 country groups

Outcomes: 1 (Blue): Very poor health, 2 (Red): Poor, 3 (Green): Fair, 4 (Orange): Good, 5 (Green): Very good. Unweighted, controlled for age, capped at 60.
Based on ordinal logit. Further analysis uses Fair/Poor/Very Poor as outcome.
Albanians are more likely to report very good health. Eastern/Transitional/developing.

Overview of measures 1

Self-reported conditions	
1. Back pain	2. Depression
3. Headache	4. Food pain
5. Arthritis	6. Stomach
7. Heartburn	8. Cold
9. Breathing	10. Headaches
11. Stomach/Intestine	12. Sleep
13. Headache	14. Sore
15. Stomach	

Health outcomes	
1. SRH	2. Any chronic illness
3. Pain	4. Cannot work
5. Disability	6. No employment
7. Work and employment conditions	8. Not healthy
	9. Other reasons
	10. Time of work
	11. Working day

Overview of measures 2

Other health issues	
1. Back pain	2. Depression
3. Headache	4. Food pain
5. Arthritis	6. Stomach
7. Heartburn	8. Cold
9. Breathing	10. Headaches
11. Stomach/Intestine	12. Sleep
13. Headache	14. Sore
15. Stomach	

Health outcomes	
1. SRH	2. Any chronic illness
3. Pain	4. Cannot work
5. Disability	6. No employment
7. Work and employment conditions	8. Not healthy
	9. Other reasons
	10. Time of work
	11. Working day

Prevalence of health outcomes and determinants using 4 country groups.

- All measures are estimated using sampling weights.
- All measures are capped at 60 years of age.
- Most measures are either binary originally, or have been dichotomized. Exceptions are noted.
- Most measures are given as prevalences in percentages within country groups.
- Estimates are divided into Greece, Albania, transitional and developing countries. Developed countries are excluded.
- Estimates have not been age standardized.
- Due to the sheer number of estimates, they have not been tested using chi-square tests.
- I will provide a few examples of gender differences.
- I will follow with more detailed analysis of some measures.

Consequences of country groupings

- One option to increase group sizes is to combine the transitional and developed countries.
- Group size increases to around 200, and the two country groups are fairly equally weighted.
- Important differences in the country groupings might disappear.

Comparison between 4 and 3 country groups (Western countries removed)

Comparing and combining transitional/developing countries

We see that country differences are reduced when collapsing.

Relative differences between genders

Some measures have notable gender differences.

Relative risks of males vs females

Effects of age capping on prevalence 1

Example with all ages

Health problems by country of birth

Supplied by Erling Landet, NTNU.

Effects of age capping on prevalence 2

Example with age capped at 60

Health problems by country of birth. Age capped at 60

Conclusion on prevalences

- Immigrants from transitional countries appear to be at higher risk of morbidity.
- Albanians overall have very good outcomes.
- Immigrants tend to have lower rates of smoking and drinking, particularly those from developing countries.
- Working conditions are worse among immigrants, likely due to the sectors they work in. MIGHEAL does not contain information on occupational class. Some information can be inferred from income and educational level, although immigrants can be overqualified.
- The estimates hide sometimes substantial gender differences.
- Age capping has a substantial effect on estimates, especially for Greece.

NATIONAL CENTRE FOR SOCIAL RESEARCH

Next: Regression analyses of health

- The prevalence rates suggest differences in several health outcomes between country groups.
- Additionally, the descriptions suggest sometimes large gender differences.
- The differential effect of age has not been taken into account in these estimates.
- The health outcomes need to be analysed by multivariate regression analysis, to account for country, gender and age differences as a minimum.

Optional: Health measures, using 3 country groups

- These measures compare Greeks, Albanians and a combined category of developed/transitional economies.
- Estimates are weighted and capped at 60.
- Developed countries have been excluded.
- All estimates and graphs in this section have been supplied by Erling Landet, NTNU.

Barriers to access in health care among migrants

MIGHEAL mid-term workshop
NTNU, November 8-9, 2016
Per Stormes, PhD student, NTNU
All estimates the graphs are based on, have been supplied by Erling Landet, NTNU.

Norwegian University of Science and Technology

Aspects of barriers to care

Barrier	Description
Discrimination	Discrimination on the basis of immigrant status.
Communication ability	Non-speaking or understanding the dominant language to communicate with health care providers. Absorbed challenges in understanding the nuances of another culture and expressing one's problems in a way that are understood and not ignored.
Knowledge of the health care system	Little knowledge about how the "system" works, what rights to health care exist, and how to navigate the health care system at all levels.

In the last 12 months, how often have you experienced discrimination or unfair treatment?	In which places or situations do you feel you have experienced discrimination or unfair treatment?
all of the time	all On the street
all of the time	all In a store, bank or restaurant
all of the time	all At work or when applying for a job or promotion
all of the time	all When dealing with the police or courts
all of the time	all In school or classes
all of the time	all When dealing with a place to live or when renting or buying a home
all of the time	all When participating in sports or recreation
all of the time	all When dealing with public transportation health care workers

Hacker, K., Arnes, M., Foll, B. L., & Zolman, L. (2015). Barriers to health care for undocumented immigrants: a literature review. *Risk management and healthcare policy*, 8, 175.

Discrimination at group level

All estimates are design weighted, and capped at 60 years of age.

Reasons for group discrimination

Discrimination at individual level

Barriers to care

Comparisons to ESS7 findings

MIGHEAL mid-term workshop
NTNU, November 8-9, 2016
Per Stormes, PhD student, NTNU
All estimates on prevalence rates and some graphs, have
been supplied by Erling Landet, NTNU.

Norwegian University of Science and Technology

A few simple examples

- Here is an example comparing MIGHEAL data (population weighted) with pooled mean ESS7 data (post stratification weighted).

Greece vs ESS average

Here is an example comparing MIGHEAL data (population weighted) with pooled mean ESS7 data (post stratification weighted).

Graph by Erling Landet, NTNU

Depression MIGHEAL vs ESS, full sample, weighted

Here is an example comparing MIGHEAL depression scores (population weighted) with ESS7 data by country total (post stratification weighted).

Graph by Erling Landet, NTNU

Optional extra material comparing ESS and MIGHEAL.

- Assumptions:**
- All rates for ESS7 have been age standardized, so they are comparable between countries.
- The rates for Greece have been weighted with population weight IMWF2.
- The rates for Greece have not been standardized, but the age distribution approximates the European Standard Population of 2013.
- All rates are split by gender, and most are given as percentages, note exceptions.
- I apologize for the poor graphs.

ESS vs MIGHEAL

The table is split by country and gender: The first bar is male, the second female. Greece to the far right (Mh). Note gender difference in Greece.

Poor / very poor health
